I'm Dr Jonathan Salo, a Cancer Surgeon at the Levine Cancer Institute.

In this video, you will learn about the treatment of metastatic esophageal cancer.

Metastatic esophageal cancer is cancer that has spread to other organs such as the liver, lungs, or bone.

The primary treatment for metastatic esophageal cancer is chemotherapy, which is usually given intravenously.

The first step will be staging scans such as a CT scan or PET scan. If you haven't done so already, please take a look at our video that talks about these scans [Advanced Esophageal Cancer](#)

The next step will be meeting with a *Medical Oncologist* to develop a treatment plan.

If you have had difficulty eating or weight loss, you may need a feeding tube to help maintain your nutrition. Please see our video on nutrition during esophageal cancer treatment [Nutrition in Esophageal Cancer](#)

Because most of the chemotherapy drugs are administered intravenously, you may need a central venous port [Central Venous Port](#)

If you or a family member have had an encounter with esophageal cancer, I would love to hear about your experience, so please take a minute to leave a comment below. We're constantly creating new videos, so please subscribe to be notified of new videos when we post them.
